

Confidence Interval Tutorial Assignment

Marc Los Huertos

October 9, 2019

One of the most important considerations with univariate data are the development of confidence intervals. As you can probably guess, confidence intervals are based on the distribution of the data. There are two main approaches in developing confidence intervals. One relies on the use of theoretical probability distributions but there are a number of methods that do not rely on theoretical distributions. We will learn several methods because each are used in environmental sciences to varying degrees.

Assignment

To create a guide for your peers about what are confidence intervals and how to create them using a univariate dataset (one set of numbers).

Using R-studio, write up an short description and demonstration of how to do a confidence interval.

Rationale

Learning statistics is challenging and teaching it even more so. But I'm convinced that we learn better if we are asked to teach a topic.

Resources

There are tons of resources to complete this assignment. For example, I have several statistics textbooks that might help you figure out how to talk about confidence intervals. There are numerous cheatsheets available, which you can get from Rstudio (Help/Cheatsheets) or from Sakai (Resources/Project 0 General Resources/Software Resources). You might look at my Guidelines to Confidence Intervals which is also linked to the Sakai page.¹

I also suggest some good videos, e.g. Khan Academy, etc.:

- Confidence intervals for proportions (Khan Academy).
- Understanding Confidence Intervals: Statistics Help

Finally, there are some good (and some terrible – Read: Wrong) resources on the web as well.

Assignment Steps

1. (1 pnt) Successfully use R-studio to create a pdf from markdown;²

Figure 1: Confidence abounds without limits.

¹ I started this guide a few days ago and it's still pretty rough, but has many of the pieces you might need!

² To open a markdown file, go to 'File/New File/R Markdown'. This will open a template for you to modify.

2. (1 pnt) Create a title, e.g. "Guide on Confidence Intervals for the Perplexed", or "What is a Confidence Interval." You can change these later if you want. Use your random number for the author name. Then select pdf to make sure your output is a pdf. You can change these later so don't worry if you don't like your title or some other choice.
3. (1 pnt) Replace the template text with a description of what is a confidence interval and how it depends on probability distributions;
4. (1 pnt) Describe "how" we talk about confidence intervals, relative to the population and sample means;
5. (1 pnt) Generate a vector of 5 random numbers with a mean of 10 and standard deviation of 1;³
6. (1 pnt) Report the sample mean and standard deviation;
7. (2 pnts) Calculate the confidence intervals for 95% and 90% and how we should report the results correctly in each case.
8. (2 pnts) Create a probability distribution that shows the confidence intervals. This is the hardest part and relies on creating a probability density curve.⁴

³ You should use `rnorm()` to accomplish this.

⁴ In my example this requires the use of `dnorm()`, where you'll need to create a dummy set of x values that encompass most of the potential x's in a sample and plot that relative to the height of the probability, calculated by `dnorm()`.

Finally, I will also grade your guide based on the clarity and robustness of your approach (2 pnts).

Working an Example

You can see that I have created a working example for myself, which you might find helpful or completely not!

here's the link for my Confidence Interval Guidelines.

As you work through your guide and find problems with mine, please point them out and I'll fix them!
